# MAPPING SHELTERBELT LAND SUITABILITY FOR MAXIMIZED ECOSYSTEM CARBON STOCKS

## No. SASK-40

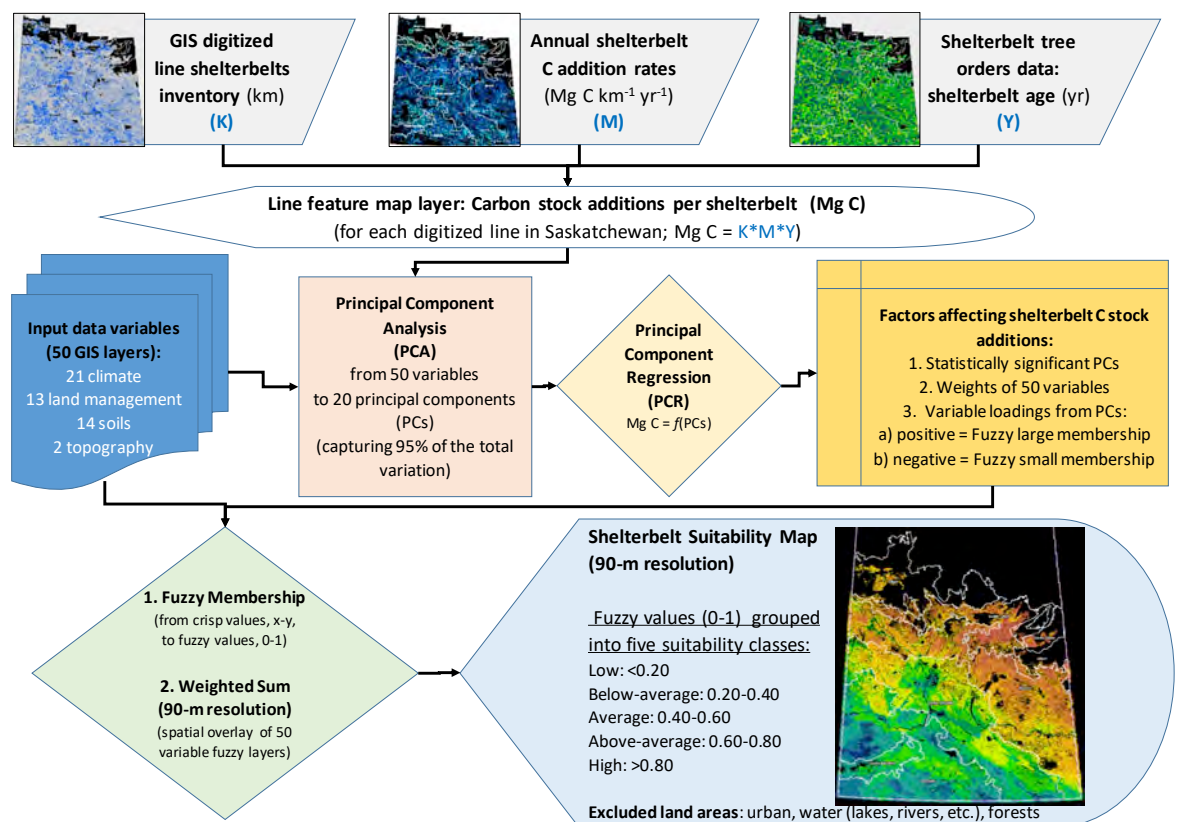

by BEYHAN Y. AMICHEV

Shelterbelts are a vital component of Canadian farms; however, guidelines are lacking to help land managers locate suitable areas for planting new shelterbelts on their landbases. Therefore, to address this knowledge gap, we created land suitability maps for deciduous, coniferous, and shrub shelterbelt establishment across a wide range of climatic and soil zones of Saskatchewan. Shelterbelt suitability mapping is a means to delineating and ranking the land across large landscapes. This comprehensive land mapping approach can benefit other afforestation and agroforestry adoption studies across Canada and the world.

### A COMPREHENSIVE LAND SUITABILITY MAPPING APPROACH

Maps of shelterbelt carbon data and 50 predictor variables were analyzed using multivariate principal component analysis (PCA), principal component regression (PCR), fuzzy logic analysis, and GIS mapping techniques. The 50 spatial datasets were used as shelterbelt establishment predictor variables (4 groups): 21 climate (1980–2010 normals), 13 land management, 14 soils, and 2 topographic criteria. The shelterbelt carbon inventory spatial layer was used as the shelterbelt establishment indicator dataset. Using PCA and PCR analyses, the overall importance (cumulative loading: positive or negative) of all predictor variables was determined and used to create shelterbelt suitability maps by means of weighted-sum overlays in GIS. Statistically significant positive correlations between mapped shelterbelt suitability levels and observed mean shelterbelt carbon stocks were used to evaluate the resulting deciduous (4.86 million hectares (Mha) study area;  $p < 0.001$ ,  $R^2 = 0.79$ ), coniferous (1.96 Mha study area;  $p < 0.001$ ,  $R^2 = 0.77$ ), and shrub suitability maps (2.06 Mha study area;  $p < 0.001$ ,  $R^2 = 0.83$ ) (Fig. 1).

Figure 1. Workflow overview of data extraction, principal component analysis, principal component regression, fuzzy membership, and weighted sum spatial analyses used to assess and map shelterbelt land suitability for maximized ecosystem carbon stocks in the agricultural region of Saskatchewan. These steps were performed separately, once each, for all planted deciduous, coniferous, and shrub shelterbelts.

## FACTORS AFFECTING SHELTERBELT C STOCK ADDITIONS

- **High ranks:** The top ranking variables affecting shelterbelt distribution were mean annual temperature, maximum annual temperature, and annual growing degree-days (GDD), all describing the temperature regime of an area. Other top-ranking variables were aridity index and mean annual precipitation, both describing the moisture regime of an area (Table 1)
- **Middle ranks:** Herbicides, fertilizer, irrigation, and tillage applications (management criteria) ranked in middle ranking positions of the overall list, emphasizing the secondary role on shelterbelt distribution, following the climate criteria. Variables from the soils and topography criteria were mostly middle and low ranking.
- **Species comparisons:** The main difference between the coniferous and the other two shelterbelt species was that the correlations for the top three variables were negative. That is, coniferous shelterbelts were predominant in areas with lower mean and max temperatures, and lower GDD (Table 1). While deciduous and shrub shelterbelts were positively correlated, meaning that they were mainly distributed in areas with higher temperatures and GDD.

→ Table 1. Ranking of 50 variables from four criteria groups (Clim = climate; Mgmt = land management; Soils = soil characteristics; Topo = topography) affecting agricultural land suitability for maximized shelterbelt ecosystem C stocks in Saskatchewan for three shelterbelt species groups (D=deciduous, C=coniferous, S=shrub). Ranks (1=highest; 50=lowest), top-third shown in bold and bottom-third as underlined values, are based on principal component analysis (i.e., variable loadings) and principal component regression (see Fig. 1). →

The suitability maps clearly delineated land of higher suitability for coniferous shelterbelts in the northern agricultural regions, while the southern regions were delineated as more suitable for deciduous and shrub shelterbelts. Additional 8.76, 7.90, and 9.77 Mha were identified across five soils zones in Saskatchewan as suitable for planting future deciduous, coniferous, and shrub shelterbelt systems, respectively, mapped as above-average or high suitability land.
